

(a) how the partition is derived

erode static + drop 4% border = ignored transition band

the window precedes drift accumulation, so the partition is not defined by the temporal failure being measured (automatic, not human-verified — see limitations)

(b) limitation: layered content

■ Ω_{static} support

■ Ω_{flow} intended motion

■ rain: assigned to one region by flow

rain crosses static support, so the same pixels are BOTH

a two-way partition cannot separate them; precipitation results carry this caveat
